Mosaic is not color balanced so tonal imbalances between individual color infrared, leaf on, 3.39 feet (1 meter) aerial survey taken during the summer of 2012. This infrared orthophotography provides many services, such as observing crop and vegetation conditions as well as supporting identification and mapping of habitat areas. The statewide distribution and collection of orthophotography provides a comprehensive and consistent set of aerial data, which can be used to create accurate, up-to-date maps. The input images are not colorfast so differences may present in the range and intensity of colors depending on the area viewed. The location and shapes of features in other GIS layers will not exactly match information shown in the orthophotography primarily due to differences in spatial accuracy and data collection dates. Street level data such as street names, U.S. routes, state routes, various railroads, and ferry crossings are displayed but may not match the locations of such features on the orthophotography. Also shown are hospitals, educational facilities, roads, rivers, and some boundaries. Important geographic locations and waterbodies are labeled.
