Soil flooding class is an important consideration for building sites, as soils prone to flooding may be unsuitable for certain types of construction. The chance of flooding is more than 50% in years with above-normal rainfall. Such areas are marked on this map.

Legend:
- Very Frequent: Flooding is likely to occur every other year under normal moisture conditions.
- Frequent: Flooding is likely to occur under normal moisture conditions. The chance of flooding is approximately 50% in any year.
- Occasional: Flooding occurs infrequently under normal moisture conditions. The chance of flooding is less than 50% in any year.
- Rare: Flooding is unlikely to occur under normal moisture conditions. The chance of flooding is less than 5% in any year.
- Not Flooded: Such areas are characterized by their low risk of flooding. The map shows the locations of these areas.

Explanation:
Soil susceptibility to flooding is determined by the presence of areas that are prone to flooding. These areas are shown in dark blue on the map. The map also shows areas that are not prone to flooding, which are shown in pink.

Data Sources:
- The soil data used in the map was provided by the U.S. Department of Agriculture's Natural Resources Conservation Service (NRCS).
- The map was created by the Connecticut Department of Environmental Protection (DEP).
