The soils were mapped at a scale of 1:12,000 with a minimum size of 10 acres. These data limitations can be easily overcome using aerial photography and satellite imagery. It is necessary to know the concerns and corrective measures, and while this map shows the rating potentials for SSDS, to understand further information such as depth to water, elevation, and other potential factors, additional studies should be conducted. This map is intended for reference only. Additional soil investigations are recommended to determine soil characteristics and suitability for subsurface sewage disposal systems.
