soils occur along watercourses occupying nearly all flood plain soil types. Wetland soils include "any of the soil types generally have a high surface water content or drainage, though not necessarily continuously saturated." They occur in the absence of water on the soil surface does not necessarily designate them as wetland soils. Wetland soils are distinguished from those of other soil classes by their characteristic wetland conditions.

DATA SOURCES

The map information is based on data collected and provided by the U.S. Geological Survey, the Connecticut Department of Environmental Protection, and the U.S. Fish and Wildlife Service. The map was generated using the U.S. Geological Survey's 7.5-minute topographic quadrangle maps published between 2000 and 2001. The map shows the general location of areas that may be upland or wetland review areas, as well as areas that may have been designated as Inland Wetlands.

DATA SOURCES

USGS 7.5 minute topographic quadrangle maps published between 2000 and 2001. The data was edited to show wetland areas. The data was slightly enlarged cartographically in order to show them at the mapped scale.

EXPLANATION

The map shows the general location of areas that may be upland or wetland review areas, as well as areas that may have been designated as Inland Wetlands.
