Very poorly drained soils generally occur on land that has a surface slope of at least 10%, and on areas with little or no soil retention capacity. These soils have a high water table and are typically subject to flooding during most of the growing season. Most of our marshes and bogs are on these soils.

The soils were mapped at a scale of 1:12,000 with a minimum size delineation of three acres. Enlargement of this map beyond the original boundaries was slightly enlarged cartographically in order to show them at this scale. All Upland review areas, nor all permanent or intermittent water bodies within a delineated wetland, are mapped on this map. This map is not colorfast.
